A child-centric microbiology education framework

Microbial Mats

Why are the coral turning black? What type of interactions are at play?

## Glossary

<table>
<thead>
<tr>
<th>Word</th>
<th>Definition</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environments</td>
<td>The surroundings or conditions in which a person, animal, or plant lives - typically only composed of abiotic (non-living) factors</td>
<td>A forest is a type of environment with trees, plants, rocks, dirt, and a river.</td>
</tr>
<tr>
<td>Strains</td>
<td>Variations (subtypes) of one microorganism species</td>
<td>The flu strain&quot; is a certain biological form of the influenza or &quot;flu&quot; virus.</td>
</tr>
<tr>
<td>Species</td>
<td>A similar living organism that can exchange genes with one another.</td>
<td>For example, two different species of animals are cows and pigs.</td>
</tr>
<tr>
<td>Microbial Mats</td>
<td>A multi-layered sheet of interacting microorganisms</td>
<td>Microbial mats typically look like a green layer on the surface or at the bottom (benthic) of a marine ecosystem (like an ocean).</td>
</tr>
<tr>
<td>Proliferate</td>
<td>Grow rapidly</td>
<td>In the summer, weeds proliferate on your lawn.</td>
</tr>
<tr>
<td>Ecosystem</td>
<td>An environment + all the living (biotic) factors in the same area.</td>
<td>A forest is an ecosystem that consists of trees, plants, rocks, dirt, a river, as well as birds, insects, small mammals, and large mammals.</td>
</tr>
<tr>
<td>Compete/Competition</td>
<td><strong>Compete:</strong> To strive to gain or win something by defeating or establishing superiority over others who are trying to do the same.</td>
<td>Two students compete with each other to win a race</td>
</tr>
<tr>
<td></td>
<td><strong>Competition:</strong> The activity of competing</td>
<td></td>
</tr>
<tr>
<td>Nutrients</td>
<td>A substance or ingredient that promotes growth, provides energy, and maintains life</td>
<td>Food!</td>
</tr>
<tr>
<td>Phenotypes</td>
<td>Physical characteristics</td>
<td>Green eyes, short legs, freckles, brown hair</td>
</tr>
<tr>
<td>Genes/Genetics</td>
<td>How certain traits and characteristics are passed from parents to offspring as a result of DNA</td>
<td>My brown hair was passed down from my mom who also has brown hair. My brother has blonde hair which was passed down from my dad because he has blonde hair.</td>
</tr>
<tr>
<td>Coexist</td>
<td>Exist at the same time and/or in the same place</td>
<td>If I can only eat fruit and you can only eat meat, we can co-exist and live together peacefully because we don’t have to compete - we want different things.</td>
</tr>
<tr>
<td>Niches/Niche</td>
<td><em>This is a tricky one. It has a few definitions</em></td>
<td>A rabbit's niche (job)  is to eat grasses which creates open areas for plants to grow in forests.</td>
</tr>
<tr>
<td></td>
<td>An organism's role in the environment, its relationship with all the biotic and abiotic (living and nonliving) factors, and the place where an organism exists comfortably.</td>
<td></td>
</tr>
<tr>
<td>Selective Forces/Pressures</td>
<td>A selective pressure is any reason for organisms with certain phenotypes to have either a survival benefit/ higher fitness or disadvantage</td>
<td>Limited food resources is a selective pressure in an environment because it causes organisms to have to compete for food. Therefore, the organisms with the best, most athletic, and strong phenotypes are more likely to survive and reproduce.</td>
</tr>
<tr>
<td>Alleles</td>
<td>Alleles are variations of a gene that can result in different traits in living things.</td>
<td>There is a “brown eye” allele that genetically codes for a person to have brown eyes.</td>
</tr>
<tr>
<td><strong>Population</strong></td>
<td>A group of individuals of the same species living and interbreeding within a given area</td>
<td>All the stray cats in New York City can be defined as a city cat population.</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Communities</strong></td>
<td>A group of species that are commonly found together (just biotic/living factors)</td>
<td>Fish, coral, and algae species are all found in a coral reef community.</td>
</tr>
<tr>
<td><strong>Industrial Environments</strong></td>
<td>An environment that consists processing materials and manufacturing various goods or products</td>
<td>E.g., Medical industry, music industry, food industry.</td>
</tr>
<tr>
<td><strong>Diverse</strong></td>
<td>Showing a great deal variety/differences</td>
<td>I like lots of different music genres; the music in my playlist is very diverse.</td>
</tr>
<tr>
<td><strong>Function(s)</strong></td>
<td>How something works/ a job</td>
<td>The clock functions well. It always shows the correct time.</td>
</tr>
<tr>
<td><strong>Survival/Survive</strong></td>
<td>To live</td>
<td>We all need food, water, and shelter in order to survive.</td>
</tr>
<tr>
<td><strong>Out-Compete</strong></td>
<td>To win something by establishing superiority over others</td>
<td>A track runner with longer legs can cover more distance faster - therefore, will be more likely to win races against other shorter track runners.</td>
</tr>
<tr>
<td><strong>Fitness</strong></td>
<td>An individual’s reproductive (baby-making) success</td>
<td>The fitness of naked mole rat (over 100 babies) is much higher than the fitness of a human (2-5 babies).</td>
</tr>
<tr>
<td><strong>Resources</strong></td>
<td>Things in an environment that are needed for organisms to survive, grow, and reproduce (make babies)</td>
<td>Some resources in an environment are air, water, food, soil, space.</td>
</tr>
<tr>
<td><strong>Agar Plate</strong></td>
<td>A circular dish with nutrients to grow bacteria on</td>
<td>A scientist used agar plates to grow the bacteria in the lab.</td>
</tr>
<tr>
<td><strong>Limited</strong></td>
<td>Not many; few</td>
<td>There are 6 kids trick-or-treating but I only have 5 candy bars. The amount of Halloween candy I have is limited.</td>
</tr>
<tr>
<td><strong>Habitat</strong></td>
<td>The area and resources used by a particular species</td>
<td>Trees provide shelter to many animals and plants within a habitat.</td>
</tr>
<tr>
<td><strong>Competitive Strategies</strong></td>
<td>Ways that a species maximizes the amount of resources it receives. This can be done by being more efficient themselves or reducing the amount of resources their competitors receive.</td>
<td>For example, algae that can grow overtop of other algae because it uses its energy to grow thicker instead of longer (like the other algae).</td>
</tr>
<tr>
<td><strong>Indirect Competition</strong></td>
<td>Two species that use the same resource but do not interact with each other</td>
<td>Some cheetahs only come out at night to drink from a water hole - this is to avoid leopards that also drink from that same water hole.</td>
</tr>
<tr>
<td><strong>Efficient</strong></td>
<td>Producing a lot with minimum wasted effort/expenses/time</td>
<td>I can do my laundry, clean my room, make dinner, and vacuum the entire house in only 20 minutes. I am an efficient cleaner.</td>
</tr>
<tr>
<td><strong>Exclude</strong></td>
<td>To prevent another species from getting a resource/ deny or prevent</td>
<td>The bar only lets people 21+ years old come inside. Everyone else was excluded from hanging out in the bar.</td>
</tr>
<tr>
<td><strong>Direct Competition</strong></td>
<td>Two species that use the same resource and fight each other to get it</td>
<td>Two monkeys are both trying to reach the largest banana at the top of a tree. They hit and shove each other off the tree so that they can reach it before the other one does.</td>
</tr>
<tr>
<td><strong>Defense Mechanism</strong></td>
<td>Ways for an organism to protect themselves</td>
<td>Thorns on a plant are a defense mechanism from organisms that eat them.</td>
</tr>
<tr>
<td>Biofilms</td>
<td>A layer of bacteria on a surface that interact with each other</td>
<td></td>
</tr>
<tr>
<td>---------------------------------</td>
<td>---------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>There can be a layer of sticky biofilm that forms on your teeth when you forget to brush them.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Antimicrobial Metabolites</td>
<td>A defensive strategies that releases a toxic substance (like poison) into the air to kill enemies</td>
<td></td>
</tr>
<tr>
<td>Some types of bacteria become toxic to defend against competitors.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Local diversity</td>
<td>The amount of species in a particular area</td>
<td></td>
</tr>
<tr>
<td>The local diversity of a fish within a small pond are other fish species. Invertebrates, and plants (grass and lily pads) in the same pond.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Top competitors</td>
<td>Species that are at the top of the food web, usually do not have any predators themselves</td>
<td></td>
</tr>
<tr>
<td>A lion is a top competitor because it has many more prey species than predator species.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Competitive exclusion principle</td>
<td>Two species can not occupy the exact same niche (use the same resources) for an extended period of time.</td>
<td></td>
</tr>
<tr>
<td>Red squirrels fit better in their environment and were better competitors than gray squirrels within Britain. Therefore, over time, more and more red squirrels replaced these gray squirrels.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Hypotheses</td>
<td>A scientific guess made by scientists when trying to solve a problem</td>
<td></td>
</tr>
<tr>
<td>I hypothesize that you will learn a lot about microbial interactions from this lesson.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Coexistence</td>
<td>Two species that live in the same ecosystem and share resources</td>
<td></td>
</tr>
<tr>
<td>My cat and I coexist in the same apartment. This is because he eats cat food and sleeps on his cat tree, and I eat human food and sleep in my bed. There is no competition, so we can easily coexist.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Burdensome gene</td>
<td>An undesirable/unnecessary gene</td>
<td></td>
</tr>
<tr>
<td>A gene that codes for a leaf on a pumpkin is unnecessary. This would be a burdensome gene because pumpkins do not need leaves to survive and reproduce.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Evolving/Evolve</td>
<td>Populations that change over time to become better adapted (have beneficial/ useful characteristics) to their environment</td>
<td></td>
</tr>
<tr>
<td>Over a long period of time, ostriches evolved to have larger bodies and feet made for running on land.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Niche/ Temporal Isolation</td>
<td>Two species that use the same resource can coexist because they use the resource at different times - can be a form of indirect competition</td>
<td></td>
</tr>
<tr>
<td>My roommate gets home before me and cooks at 6PM. I get home at 8PM to cook. We never have to fight over kitchen space.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Multi-Species Assemblage</td>
<td>A collection of multiple species</td>
<td></td>
</tr>
<tr>
<td>Many different microorganisms make up your intestines (in your gut).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Reproduce</td>
<td>Passing down one's genes through having an offspring</td>
<td></td>
</tr>
<tr>
<td>When a mommy and daddy love each other very much they make babies (reproduce).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Detrimental</td>
<td>When something has a negative effect, harmful</td>
<td></td>
</tr>
<tr>
<td>A hot summer day is detrimental to an ice cream cone.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Agriculture</td>
<td>Farmers planting and harvesting vegetables to feed people</td>
<td></td>
</tr>
<tr>
<td>Growing corn.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Negative Interactions</td>
<td>Interactions between organisms that are harmful</td>
<td></td>
</tr>
<tr>
<td>Two frogs compete for sunlight by pushing each other off a log.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Positive Interactions</td>
<td>Interactions between organisms that are beneficial</td>
<td></td>
</tr>
<tr>
<td>Birds/rhinos have a mutualistic relationship. Birds eat parasites off of the rhino while providing food for the bird.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Mutualistic</td>
<td>Positive/Positive Interaction in which two species are benefiting each other</td>
<td></td>
</tr>
<tr>
<td>I will help you edit your homework if you help me hand out flyers to my birthday party. Both people benefit - this is mutualistic.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Commensalism</td>
<td>Positive/Neutral Interaction in which one species is benefiting while the remains the same</td>
<td></td>
</tr>
<tr>
<td>Whales provide a place for barnacles to grab onto while not harming the whale</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
<td>Example</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Predation</td>
<td>Positive/Negative Interaction in which one species eats the other for energy</td>
<td>The lion preys on the gazelle and eats him.</td>
</tr>
<tr>
<td>Parasitism</td>
<td>Positive/Negative Interaction in which one species sucks the energy out of the host</td>
<td>A tick parasitizes a dog for nutrients.</td>
</tr>
<tr>
<td>Implication</td>
<td>A connection/involvement/consequence</td>
<td>An implication of driving without a seatbelt is getting harmed in a car crash.</td>
</tr>
<tr>
<td>Modern Medicine</td>
<td>Current substances/techniques used to treat illnesses</td>
<td>If you break your arm, modern medicine can use a machine called a CT scan to see very detailed images of the broken bone. This will allow for proper healing.</td>
</tr>
<tr>
<td>Antibiotic Resistance</td>
<td>Antibiotics kill 99% of bacteria, the 1% that remain have defenses against the antibiotic. This is usually due to previous exposure to that same antibiotic (your body got used to it, so it doesn’t help much anymore).</td>
<td>If a cow gets sick and the farmer wants it to stay alive so that it can continue to grow, he might give the cow an antibiotic. Later, a little boy eats a burger made from that cow. The antibiotic that the cow ate is now in the little boy. Let’s say the little boy gets an ear infection and goes to the doctor and gets prescribed an antibiotic to get better. The antibiotic doesn’t work because the little boy’s body is used to that antibiotic (from the cow he ate!) This means he has developed antibiotic resistance to that specific antibiotic. The doctor has to prescribe him a different antibiotic (one that his body isn’t already used to), so that he gets better!</td>
</tr>
<tr>
<td>Antibiotics</td>
<td>Medicine used to get rid of bacteria in the body</td>
<td>Amoxicillin is a type of antibiotic used to treat chest infections/colds.</td>
</tr>
<tr>
<td>Antibodies</td>
<td>In your body, there are Y-shaped proteins (antibodies) used by the immune system to identify and kill things that your body isn’t used to (such as a virus or bacteria). Your body remembers the antibodies used to kill off these strange viruses or bacteria and stores them to use if that specific virus or bacteria comes back</td>
<td>IgG is the name of a very common antibody in your body. It is found in the blood. It helps your body fight off cancer.</td>
</tr>
<tr>
<td>Resistant Strain</td>
<td>A type of bacteria that is not killed by antibiotics</td>
<td>MRSA is a type of bacterial infection that often is resistant to antibiotics, making it hard to treat.</td>
</tr>
<tr>
<td>Overuse</td>
<td>Using something too much/often</td>
<td>I wore the same pair of shoes everyday for 12 years, even when they began to fall apart. This caused my feet to be very sore. I overused that pair of shoes.</td>
</tr>
<tr>
<td>Repetitive Exposure</td>
<td>Coming into contact with something more than once</td>
<td><em>See cow and little boy example above</em></td>
</tr>
<tr>
<td>Multitude</td>
<td>A large number of/many</td>
<td>There are a multitude of microbes in this world.</td>
</tr>
<tr>
<td>Avoid</td>
<td>To keep/stay away from something</td>
<td>You often hide from your mom when she asks you to clean your room.</td>
</tr>
</tbody>
</table>
An Introduction

Once upon a time, two brightly colored fish were swimming alongside each other and caught each other’s eye. They quickly fell in love and got married within a beautiful, glowing coral reef. A few years later, they had a little fish named Nemo. Nemo loved to visit the coral reef where his parents got married and listen to their wonderful love story. His favorite part of the reef was the vibrant colors: pink, yellow, blue, purple — and Nemo’s personal favorite — orange. On Nemo’s daily swim to school, he would pass by the coral reef on his way to Mr. Ray’s class. Nemo loved to point out his favorite spot in the ocean to which his classmates would ooh and ahh at the lovely colors. One day, out of the blue, Nemo noticed an unfamiliar black spot on his favorite orange coral within the reef. The spot was very small, so he didn’t worry too much about it at first and continued his swim to class. Over the next few days, however, the black spot seemed to grow! Nemo was very concerned to see the black spot growing so quickly, so he decided to ask Mr. Ray.

“Mr. Ray, why are there black spots on my coral?” Nemo asked, concerned. Mr. Ray gave a small frown. “Well Nemo, unfortunately, there is something called a microbial mat on the coral. Can everyone say microbial mat?” “Mi-cro-bi-al mat!” chants the class “Excellent pronunciation” says Mr. Ray, “These microbial mats house tiny little organisms — called microbes — that live in layers like a big sandwich. The organisms have been alive for a very long time - they are even older than me!” The class gasps, because Mr. Ray must be a thousand years old, “Well, what are microbial mats made of?” Nemo asks, eyebrows furrowed. “Microbes are made of cells, just like you and me. Microbial mats have many types of microbes, like bacteria and archaea, interacting with each other. The mats help with making super important compounds, like carbon and oxygen, and without these, we wouldn’t be alive! But you’ll learn more about that in high school...” Mr. Ray smirks.

“Okay...” Nemo thinks, “So why are they turning my coral black?” “Great question, Nemo. These mats sometimes provide a home for bad bacteria. When this happens, the bad guys take over the coral and make it sick. Unfortunately, there aren’t very many good coral doctors, so the pretty colors start to turn black.”Nemo’s eyebrows furrow, “NO! My favorite coral is sick?! But, why did this happen?” Mr. Ray sighs, “I know, Nemo. I’m sorry. Up on the surface, there are lots of things that humans do that change our beautiful home down here - these things cause the seawater temperature to change and also causes lots of pollution. These all contribute to microbial mat changes that can hurt coral.”

“People like Darla?” Nemo asked, recalling his adventure on the surface. “Yes. People like Darla. But remember, Nemo, these changes aren’t just because of one person. It’s the combination of lots of people's behaviors and actions.” Mr. Ray pauses, then continues, “Also, the reason it spreads so quickly on the coral is because there are a lot of coral living next door to each other - the bad bacteria can hop from coral to coral very easily.” Mr. Ray smiles softly “It’s unfortunate, but each human can do their part to reduce pollution and help stop the spread.” “So what can WE do to help?!” Nemo exclaims, his mood lifting. “Right now, there’s not much we can do, but you can keep asking great questions - and one day grow up to answer them!” Nemo grins, “Rad! I can’t wait to be the best scientist ever one day. I am going to stop humans from causing pollution and find a cure for my favorite coral reef!”

“If anyone can do it, it’s you, Nemo!” Mr. Ray exclaims, and the class cheers.
Microbial Interactions

Overview:

Microbes, also known as microorganisms, are extremely small living organisms that can only be seen using a microscope. Microorganisms live in many different environments, surrounded by various strains and/or multiple different species entirely. Some examples of microorganisms include viruses, bacteria, fungi, protozoa, and archaea. There are tons of interacting microbial species in the world, which sometimes form thick, multi-layered structures called microbial mats. These mats sometimes proliferate (or grow) depending on the environmental conditions. When they grow near coral reefs, the “bad bacteria” in the mat sometimes jump onto the coral, causing a disease. This disease may spread quickly from corals near one another, which is very bad for the coral reef ecosystems.

The interactions within these mats can be very complex. Many different types of interactions between the microbes occur - the most common of these being competition. Different strains and species of microorganisms have to compete against each other for nutrients and space. This challenge has caused microbes to change their phenotypes over time to compete against the other microbes in the same space. This competition is common but decreases over time as the various genetically distinct microbes learn to coexist. The specific niches that different types of microbes thrive in play a huge role in their selective forces, which cause certain alleles to become more common within a population over time. This lesson plan highlights the interactions between microbes to better predict future behaviors of microbes. These behaviors can then be applied to real-life settings, giving us insights on how microscopic communities can work with us, rather than against us, in both natural and industrial environments.

Microbial Competition:

The Nature of Competition:

Microbes are extremely diverse. They all have different functions and live in various places. In a mat, there are usually many different types of microbes all living together, and they are in a constant battle for food, space, and overall survival - this battle is called competition. If a microbe is strong enough to out-compete the other microbes and make lots of babies, it has a high fitness and passes on its genes successfully!

Competition Between Microbes is Widespread

When different kinds of microbes live together, they often have to compete for the same resources. This can be seen in experiments where scientists put different microbes found in nature onto the same agar plate. There are multiple reasons why microbes often compete with each other namely:
1. When microbes want the same, limited food source.
2. When microbes are all living in the same, small space.
3. When there are a lot of microbes, but not a lot of resources.

The types of microbes that compete with one another is wide-spread. However, one common trend seen is that, if microbes are related to each other, they are more likely to compete because they want the same type of food, habitat, and other resources. They are also likely to have similar competitive strategies.

**Competitive Phenotypes & Strategies:**

Microbes compete with each other both directly and indirectly. In indirect competition, microbes compete to get the resources they need without directly coming in contact with one another. For example, some microbes may have phenotypes that contribute to them being faster when collecting resources. This type of phenotype allows them to take all the resources they need first, leaving fewer nutrients for slower, less efficient microbes. Microbes may also indirectly compete for the best location to live in. By establishing themselves in this perfect location, they take up space and exclude their competition from entering the same space.

On the other hand, in direct competition, microbes physically clash against each other - damaging one another. The microbes with phenotypes of larger, stronger body sizes allow them to win against smaller, weaker microbes. A defense mechanism that microbes have is their ability to create biofilms, which act as a shield against harmful enemies and environments. Microbes can also release antimicrobial metabolites, which act as a poison released into the air, killing enemies. Microbes with competitive phenotypes allow it to have a large number of competitive strategies and defense mechanisms, making it a stronger competitor as well as a larger threat within its environment.

**Consequences of Competition Over Time - Coexistence:**

Local diversity consists of all the species found within your nearby habitat. When multiple species of microbes live in the same area and use the same resources, they will compete with each other. Eventually, the top competitors will be the only ones left in the area, this is called the competitive exclusion principle. Although the competitive exclusion principle is often seen in natural settings, there are still some ways in which multiple microbe species can live together. Scientists have found various hypotheses for this coexistence, a few of these being:

1. The **Black Queen Hypothesis**:

   This states that, sometimes, top competitors not only allow other microbes species to exist within the same areas as them, they actually need and rely on these other microbes species in order to survive. One hypothesis for why this occurs is because some microbe species lose burdensome genes over time when they no longer have to perform these specific functions for themselves.
Therefore, even if the microbes who can perform that specific function aren’t good competitors, they will remain in an area because the other microbes need them.

For example, let’s say there is a super big, strong, athletic mouse and a super small, weak mouse. The big mouse can fight off all the predators, which also keeps the small mouse safe. However, the small mouse is still taking up space and food that the big mouse could be using for himself. The question is, why does the big mouse keep the small mouse around? Well, the big mouse has grown so big and strong that when it is time to creep into small places for food, it can no longer fit! It used to be able to fit, but the mouse got bigger over time. This is where the little mouse comes into the picture; he can fit through almost any hole, making it larger from the inside until the big mouse can come inside. Similar to the microbes, the small mouse has a function that the big mouse had lost over time. This function (squeezing into small places) is important for the big mouse as well. Because of this, he doesn’t chase away the small mouse, and instead, they work together to survive.

2. The Red Queen Hypothesis:

Competing microbes often go through many evolving processes. If one species can continue to evolve with another species, they can continue to compete with each other. This leads to coexistence because one species is unable to completely beat out the other species. For example, imagine you bought a new pair of new shoes. With them on, you can run fast and easily beat everyone in a race at recess time. You flew past all the other students! However, the next day another student has even newer, faster shoes than you. You try your absolute hardest to win, and you both fly past the other students, but unfortunately, the other student pulls through and wins the race. Can you guess what you do? The next day you come in with even newer shoes, and the race begins again. This is similar to microbes evolving in the Red Queen Hypothesis. They have to keep evolving to “keep up” with their competition – in doing so, multiple species can continue to coexist.

3. Niche/Temporal Specialization

This hypothesis is easy. Microbial species can coexist when either the time periods or physical area in which they exist do not overlap. For example, there could be many species of microbes living on a rock within a river bed. Species 1 only comes out at night and species 2 only comes out in the daytime. These species never run into each other due to this temporal difference, and therefore, they coexist. This specialization may occur over time as species learn when and where they can “come out” and not get killed by other species.

Concluding Remarks

In conclusion, the microbial community is just a multi-species assemblage of microbes living in the same shared environment. Just like us as humans, these organisms need food and other resources to survive and reproduce. Sometimes there are not enough resources in the area, so organisms have to compete with one another for these limited resources. Competition for
resources happens for multiple reasons, in both direct and indirect ways. Certain phenotypes will allow for species to have increased competitive and/or defensive strategies – and therefore allow them to out-compete the other species. Over time, however, there have been consequences of competition that allow for increased coexistence between different microbial species.

Follow-Up Discussion Questions

Basic:
1. How are microorganisms different from other organisms?
2. What is an example of a way microbes might compete with other microbes?
3. What is an example of a phenotype that both a person and microbe might share?
4. What would happen if a big, fast squirrel wanted the same acorn as a small, slow squirrel? Who do you think would win and why?
5. You just learned how microbes are diverse, can you think of a way in which people are also diverse?
6. Can microbial mats hurt coral? How?

Advanced:
7. When might microbes stop competing for resources?
8. What is one reason why microbes compete? What do you compete for?
9. Can you create another “Black Queen Hypothesis” example?
10. Do you think microbial interactions might differ depending on the environment they live in? Why or why not?
11. Do you think competitive strategies or defensive mechanisms are more important? Why?
12. How might microbes be detrimental within an industrial environment?

A Deeper Dive into Microbial Interactions - Bacteria

Overview:
Bacteria are a specific type of microorganism. Like many other microbes, they often live in diverse, interacting communities. The interactions between different bacteria are important to understanding how bacteria survive and reproduce. Understanding bacteria has important implications for human health, agriculture, and industry. Across environments, microbes like bacteria can interact with each other and other organisms in positive, negative, and neutral ways; these interactions are largely dependent on the conditions of the current environment. Despite this, research has found that negative interactions are more common than positive interactions.

For example, think of interactions of a family living in a house together. The house is like the environment, there are a lot of factors to consider (food in the fridge, the number of beds and bathrooms). If there is plenty of food and space in the house, you and your family might get along great. However, if your parents have a new baby, there is now less space, so you and your siblings might fight over who has to share a room and who gets the last candy bar. Like bacteria...
and other microbes, these interactions can shift from positive to negative or vice versa. Now, let’s dive into the specifics of these interactions!

Types of Interactions (and Examples):

1. Mutualistic (+/+): Both species benefit from the interaction. Example: Oxpeckers (birds) and zebras. Oxpeckers eat parasites and bugs that land on the zebra’s back - this helps the zebra stay clean. This is also beneficial to the oxpecker because they can easily find food (zebras are easy to see).
2. Commensalism (+/0): One species benefits and the other species doesn’t benefit, but also isn’t harmed. Example: A bird making a nest in a tree. The bird receives shelter from the tree. The tree is neither harmed nor benefited by the nest.
3. Predation (+/-): One species benefits and the other one is harmed. One species consumes the other species. Example: Wolves hunt and eat moose. This helps the wolves by providing them with energy in the form of food, but hurts the moose because it kills them.
4. Parasitism (+/-): One species benefits and the other one is harmed. One species uses the other species body (the host) to survive. Example: Tapeworms inside the intestines of a cow. Tapeworms eat the cow’s slightly digested food which helps them attain food, but harms the cow through the loss of nutrients.
5. Competition (-/-): Both species/organisms are harmed. Example: multiple bacteria species on a single agar plate competing with each other (and killing each other) for the limited space.

A Modern Day Implication to Bacterial Interactions

An important issue relating to bacteria interactions in modern medicine comes from something called antibiotic resistance. Remember how there is bad bacteria out in the natural world that makes organisms sick (for example, the bacterial disease that makes Nemo’s favorite coral black and sick)? Modern medicine makes antibiotics, which are made of antibodies, that fight against these bad bacteria. However, sometimes the bad bacteria can change in response to antibiotics. This usually happens over time, causing the “new” bad bacteria to no longer be killed by the antibodies, making it a resistant strain. Antibiotic resistance can happen in all types of organisms, including humans, due to an overuse and/or repetitive exposure to antibiotics, which allows bacteria to get familiar with the medicine and find ways to fight against it. Understanding the interactions of different microbes, specifically bacteria, may give us insight into how they compete against certain antibodies. This teaches us more about antibiotic resistance and how to stop it from occurring in the future.
Concluding Remarks

Bacteria species are a great example of microbial interactions. There are many factors that determine whether species interactions are positive, negative, or neutral - some of these factors include the type of species being studied, resource availability, previous interactions, how close the species are to one another, and so on. The interactions between and among species can typically be described as mutualistic (both benefit), commensalistic (one benefits and the other is unaffected), predation or parasitism (one benefits and the other is harmed), or competition (both are harmed). Although the beginning of this lesson focused on competition as a microbial interaction, it is important to be aware of the multitude of interactions that could occur, and how these interactions shift and change depending on the type of microbe, its function, and the ecosystem it lives in.

Discussion Questions

Basic

1. Can you name one specific type of microbe/microorganism?
2. What type of interaction is mutualism?
3. If you were a microbe, what is one thing you would do to avoid bad interactions?

Advanced

1. Can you think of an example of antibiotic resistance that affects humans?
2. What are ways the environment might be influencing the behavior of bacteria?
3. What is the word we used to define a neutral interaction where one species benefits and the other is unaffected? Can you think of an example?
4. Do you think negative or positive interactions are more common among bacteria in the environment? Why?
5. What kind of interaction relates to the coexistence of microorganisms? Why do you think this?
